CS50, vid 4

Shorts 1: Conditionals
have the program ask questions and take different courses/behaviors depending on the answers to those questions.

if → Some statement/Variable is evaluated as true/false to determine its behavior
True → if statement is run (Stuff within if statement)
False → if statement is not run (Stuff within if statement not run)

Shorts 2: Boolean expressions
Utilizing Boolean operators:
not, and, or

not negates the value of a boolean expression

or also represents "either" (but don't use "either" as a keyword)
and chooses True as long as a true statement exists

and is to state that two or more statements must ALL be True to pass a true statement. If one or more statements are False, and statement makes everything false

return ends a function, even with nothing in it
